

Tidy Data and Tidying Data

Maria Barouti

Based on lecture handouts originally written by Dr. David Gerard.

Learning Objectives

- What is tidy data?
- Learn to make your data tidy with `gather()`, `spread()`, `separate()`, and `unite()`.
- [Data Import Cheat Sheet](#)
- [Tidyr Overview](#).

Tidy Data

- Recall:
 - Observations/units/subjects/individuals/cases: objects described by a set of data (e.g. cars, people, countries).
 - Variable: describes some characteristic of the units (e.g. mpg, age, GDP).
 - Each unit has a single value of each variable (e.g. 20 mpg, 31 years old, 20,513,000 US million).
- Tidy Data:
 - One unit per row.
 - One variable per column.
 - One value per cell.
- Hadley's visualization:

- We will use the tidyr package (a member of the tidyverse) to make data tidy.

```
#install.packages("Sleuth3")  
library(tidyverse)
```

```
## Warning: package 'tidyverse' was built under R version 4.0.5
```

```
## Warning: package 'tibble' was built under R version 4.0.5
## Warning: package 'tidyr' was built under R version 4.0.5
## Warning: package 'dplyr' was built under R version 4.0.4
## Warning: package 'forcats' was built under R version 4.0.5
```

- Example of tidy data:

```
#Below we will see datasets that demonstrate multiple ways to layout the same
#tabular data ex:table1,2,3,4a,4b,5.
tidyr::table1 #:: allows you to access the exact function from the specific package
```

```
## # A tibble: 6 x 4
##   country      year  cases population
##   <chr>      <int> <int>      <int>
## 1 Afghanistan 1999     745   19987071
## 2 Afghanistan 2000    2666   20595360
## 3 Brazil      1999   37737   172006362
## 4 Brazil      2000   80488   174504898
## 5 China       1999  212258  1272915272
## 6 China       2000  213766  1280428583
```

- Variables: Country, Year, Cases, Population
- Units: location×time

- Untidy data: Each unit is spread across multiple rows

```
print(tidyr::table2, n=12)
```

```
## # A tibble: 12 x 4
##   country      year type      count
##   <chr>      <int> <chr>      <int>
## 1 Afghanistan 1999 cases         745
## 2 Afghanistan 1999 population 19987071
## 3 Afghanistan 2000 cases         2666
## 4 Afghanistan 2000 population 20595360
## 5 Brazil      1999 cases         37737
## 6 Brazil      1999 population 172006362
## 7 Brazil      2000 cases         80488
## 8 Brazil      2000 population 174504898
## 9 China       1999 cases         212258
## 10 China      1999 population 1272915272
## 11 China      2000 cases         213766
## 12 China      2000 population 1280428583
```

- Untidy data: Two variables are in one column

```
tidyr::table3
```

```
## # A tibble: 6 x 3
##   country      year rate
## * <chr>      <int> <chr>
## 1 Afghanistan 1999 745/19987071
## 2 Afghanistan 2000 2666/20595360
## 3 Brazil      1999 37737/172006362
## 4 Brazil      2000 80488/174504898
## 5 China       1999 212258/1272915272
## 6 China       2000 213766/1280428583
```

- Untidy data: Data are spread across two data frames. Within each data frame, multiple units are in one row.

```
tidyr::table4a
```

```
## # A tibble: 3 x 3
##   country    `1999` `2000`
## * <chr>      <int>  <int>
## 1 Afghanistan    745   2666
## 2 Brazil        37737  80488
## 3 China         212258 213766
```

```
tidyr::table4b
```

```
## # A tibble: 3 x 3
##   country    `1999`    `2000`
## * <chr>      <int>      <int>
## 1 Afghanistan 19987071 20595360
## 2 Brazil     172006362 174504898
## 3 China      1272915272 1280428583
```

- Sometimes it is easy to determine the units and the variables.
- Sometimes it is very hard and you need to talk to the data collectors to find out.
- We want tidy data because R easily manipulates vectors. So in the long run it will make your life easier to first make data tidy.

Gather

- Problem: One variable spread across multiple columns.
- Column names are actually *values* of a variable
- `table4a` and `table4b`
- Solution: `gather()`
- Hadley's visualization:

country	year	cases
Afghanistan	1999	745
Afghanistan	2000	2666
Brazil	1999	37737
Brazil	2000	80488
China	1999	212258
China	2000	213766

table4

- Specify
 - The columns that are values, not variables,
 - The name of the variable that will take the values of the column names (**key**), and
 - The name of the variable that will take the values spread in the cells (**value**).

```
tidy4a <- gather(table4a, `1999`, `2000`, key = "Year", value = "cases")
tidy4a
```

```
## # A tibble: 6 x 3
##   country      Year  cases
##   <chr>      <chr> <int>
## 1 Afghanistan 1999     745
## 2 Brazil      1999    37737
## 3 China       1999   212258
## 4 Afghanistan 2000     2666
## 5 Brazil      2000    80488
## 6 China       2000   213766
```

```
tidy4b <- gather(table4b, `1999`, `2000`, key = "Year", value = "population")
tidy4b
```

```
## # A tibble: 6 x 3
##   country      Year population
##   <chr>      <chr>      <int>
## 1 Afghanistan 1999    19987071
## 2 Brazil      1999    172006362
## 3 China       1999   1272915272
## 4 Afghanistan 2000    20595360
## 5 Brazil      2000    174504898
## 6 China       2000   1280428583
```

- We will learn next class how to join these two data frames next week. But the code is

```
full_join(tidy4a, tidy4b)
```

```
## Joining, by = c("country", "Year")
```

```
## # A tibble: 6 x 4
##   country      Year  cases population
##   <chr>      <chr> <int>      <int>
## 1 Afghanistan 1999     745    19987071
## 2 Brazil      1999    37737   172006362
## 3 China       1999   212258   1272915272
## 4 Afghanistan 2000     2666    20595360
## 5 Brazil      2000    80488    174504898
## 6 China       2000   213766   1280428583
```

- **Exercise:** gather the `monkeymem` data frame . The cell values represent identification accuracy of some objects (in percent of 20 trials).

Spread

- Problem: One observation is spread across multiple rows.
- One column contains variable names. One column contains values for the different variables.
- `table2`
- Solution: `spread()`
- Hadley's visualization:

- Specify:
 - The column that contains the column names (**key**), and
 - The column that contains the values (**value**).

```
tidy2 <- spread(table2, key = "type", value = "count")
tidy2
```

```
## # A tibble: 6 x 4
##   country      year  cases population
##   <chr>      <int> <int>      <int>
## 1 Afghanistan 1999     745    19987071
## 2 Afghanistan 2000    2666    20595360
## 3 Brazil      1999   37737   172006362
## 4 Brazil      2000   80488   174504898
## 5 China       1999  212258  1272915272
## 6 China       2000  213766  1280428583
```

- Exercise:** Spread the `flowers1` data frame.

Separate

- Problem: One column contains two (or more) variables.
- `table3`
- Solution: `separate()`
- Hadley's visualization:

- Specify:
 - The column that contains two (or more) variables,
 - A character vector of the new names of the variables, and
 - The character that separates variables (or the position that separates variables).

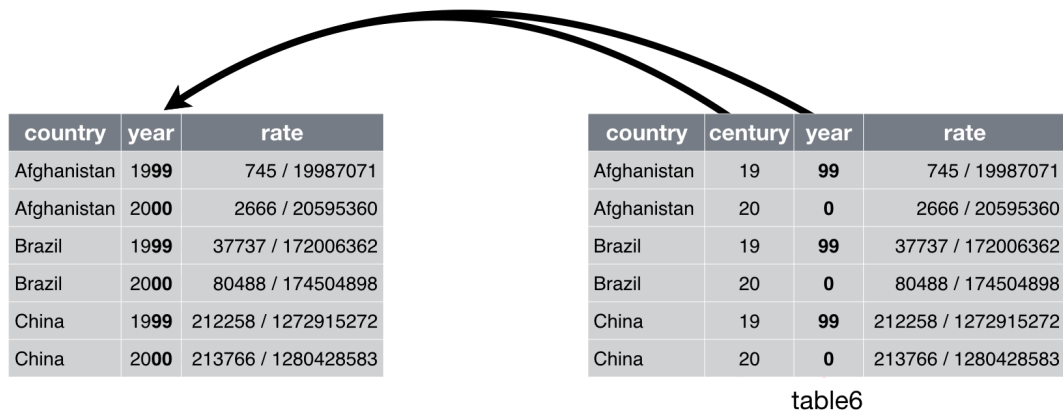

```
tidy3 <- separate(table3, col = rate, into = c("cases", "population"), sep = "/")
tidy3
```

```
## # A tibble: 6 x 4
##   country      year cases population
##   <chr>      <int> <chr>   <chr>
## 1 Afghanistan 1999 745     19987071
## 2 Afghanistan 2000 2666    20595360
## 3 Brazil      1999 37737   172006362
## 4 Brazil      2000 80488   174504898
## 5 China       1999 212258  1272915272
## 6 China       2000 213766  1280428583
```

- Exercise:** Separate the `flowers2` data frame.

Unite

- Problem: One variable spread across multiple columns.
- Solution: `unite()`
- Hadley's visualization:

- Much less common problem.

table5

```
## # A tibble: 6 x 4
##   country    century year  rate
## * <chr>      <chr>   <chr> <chr>
## 1 Afghanistan 19      99    745/19987071
## 2 Afghanistan 20      00    2666/20595360
## 3 Brazil      19      99    37737/172006362
## 4 Brazil      20      00    80488/174504898
## 5 China       19      99    212258/1272915272
## 6 China       20      00    213766/1280428583
```

- Specify:
 - i. The name of the new column (col),
 - ii. The columns to unite, and
 - iii. The separator of the variables in the new column (sep).

```
tidy5 <- unite(table5, century, year, col = "Year", sep = "/")
tidy5
```

```
## # A tibble: 6 x 3
##   country    Year  rate
##   <chr>      <chr> <chr>
## 1 Afghanistan 1999  745/19987071
## 2 Afghanistan 2000  2666/20595360
## 3 Brazil      1999  37737/172006362
## 4 Brazil      2000  80488/174504898
## 5 China       1999  212258/1272915272
## 6 China       2000  213766/1280428583
```

- **Exercise:** Re-unite the data frame you separated from the `flowers2` exercise. Use a comma for the separator.
